7.2.2003.6.21.0108.0118.1. Field of the Invention The present invention relates to a musical sound signal synthesizer that generates an original musical sound waveform having a frequency different from a tone waveform generated by a tone

generator. 2. Description of the Prior Art As a device that generates a musical sound waveform of a given frequency range with a relatively low frequency (pitch), the following techniques have been proposed. In the prior art techniques, a mathematical function that is used as a function for generating musical sounds is defined by two parameters, i.e., an amplitude and a frequency and these two parameters are varied to generate a musical sound waveform of a given frequency. That is, a value of a waveform at a given point on the time axis is calculated according to a mathematical function which is used for generating musical sounds. Then, the amplitude of this value is varied (converted into a modulation amount) to determine a value on the time axis, thus generating a waveform. This mathematical function can be realized by the use of an LUT (Look Up Table) which stores a value of a function corresponding to each value of the two parameters and a state of the function at each value of the two parameters. The LUT is stored in a ROM (Read Only Memory), for example. In a synthesizer using such a mathematical function to generate musical sounds, the mathematical function can be realized by a process which is as follows. First, a value of a waveform at a given point on the time axis is calculated according to the mathematical function. Then, the value is multiplied by a modulation amount and the multiplication result is added to a value which is obtained when a value of a waveform at a given point on the time axis is calculated according to the mathematical function. In this manner, a waveform having a waveform value multiplied by the modulation amount is generated. In the above method, a piece of information corresponding to a value of the mathematical function for calculating a waveform value at a given point on the time axis is required to be stored in a ROM. For example, information corresponding to all of the points on the time axis is required to be stored in the ROM. In this manner, since information corresponding to a value of the 82157476af
